1 Using Recommender Systems

Student name: Jonathan Lee

Student pace: Full Time

Scheduled project review date/time: June 22, 2pm

Instructor name: James Irving

Blog post URL:

1.1 Overview

This project uses the Surprise package from scikit with Amazon review data of Luxury Beauty products to build a recommendation system. In this analysis, we find that out of KNN methods, Singular Value Decomposition, and Alternating Least Squares methods, Singular Value Decomposition was the best performing model for our selected data. We also examine what the optimal hyperparameters are for this particular dataset.

1.2 Business Problem

Our client is a beauty product retailer that wants to know what the most popular products on Amazon are, as well as what other products customers would be likely to give high ratings to, under the assumption that they would give high ratings to these popular products. We want to optimize a recommender system based on Amazon reviews that as accurately as possible predicts other products that customers would be likely to enjoy. Using this optimized recommender system, we will move forward with the goal of using our client's customer preferences to extract insights into what other brands/products would be successful if our client were to add them to their product offering. **Questions to address:** What is are the optimal model and hyperparameters to build a recommender system to work with Amazon ratings dataset to provide recommendations for our own customers? * What are Amazon's most popular products in terms of number of ratings? * Assuming that our client's customers currently give high ratings to the popular products on Amazon, what other products can we recommend adding to inventory? *

1.3 Data Understanding and Preparation

In this analysis, we use Amazon review data and product metadata featured in the following paper: **Justifying recommendations using distantly-labeled reviews and fined-grained aspects**

Jianmo Ni, Jiacheng Li, Julian McAuley

Empirical Methods in Natural Language Processing (EMNLP), 2019

Due to the large size of the complete dataset and hardware limitations, we will complete the analysis with only reviews and metadata from the luxury beauty product category.

Let's begin by loading in our data and doing some Exploratory Data Analysis.

```
[1]: # Import standard packages
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns

np.random.seed(27)

%matplotlib inline
```

```
[2]: # Set theme and style for plots
sns.set_theme('talk')
sns.set_style('darkgrid')
```

1.3.1 Loading in the Data

We have two tables to work with in this analysis: 1. Review data: contains product ASIN code, user code, and the rating that user provided. 2. Product metadata which includes all product metadata including price, product name, and product images paired with ASIN codes.

```
[3]: # Load review dataset and metadata
review_df = pd.read_csv('data/Luxury_Beauty.csv', names=['asin', 'user', 'rating', 'timestamp'])
meta_df = pd.read_json('data/meta_Luxury_Beauty.json.gz', lines=True)
display(review_df, meta_df)
```

1.3.2 Dropping Duplicates and Null Values

We are dealing with quite a large dataset, with the number of ratings being over 570,000. Therefore, it will be important to reduce the memory as much as possible by removing unnecessary features and reducing the memory usage. Since the timestamp data is unnecessary to our analysis, we will go ahead and drop that column from our ratings dataset. We also go through an initial iteration of removing duplicates and null values.

```
[4]: # Drop duplicates and timestamp column from review table
review_df.drop_duplicates(inplace=True)
review_df.drop('timestamp', axis=1, inplace=True)
review_df
```

```
[4]:
```

	asin	user	rating
0	B00004U9V2	A1Q6MUU0B2ZDQG	2.0
1	B00004U9V2	A3H02SQDCZIE9S	5.0
2	B00004U9V2	A2EM03F99X3RJZ	5.0
3	B00004U9V2	A3Z74TDRGDOHU	5.0
4	B00004U9V2	A2UXFNW9RTL4VM	5.0
...
574623	B01HIQEOL0	AHYJ78MVF4UQ0	5.0
574624	B01HIQEOL0	A1L2RT7KBNK02K	5.0
574625	B01HIQEOL0	A36MLXQX9WPPW9	5.0
574626	B01HJ2UYOW	A23DRCOMC2RIXF	1.0
574627	B01HJ2UY1G	AJEDVHTLS9P3V	5.0

[538082 rows x 3 columns]

Similarly with our metadata, we will go ahead and slice out the ASIN code and product names, since those are the pieces of data that will be used in our analysis. Then, we go on to drop duplicates from this table as well.

```
[5]: # Slice asin and title columns from metadata table
meta_df = meta_df[['asin', 'title']]
```

```
[6]: # Drop duplicates from metadata table
meta_df.drop_duplicates(inplace=True)
meta_df
```

```
[6]:
```

	asin	title

[12111 rows x 2 columns]

1.3.3 Merging Data Tables

Now, we will create a `catalog_df` which contains all of our ratings combined with their titles. This dataframe contains all of the information we will need for the purpose of our analysis.

```
[7]: # Combine review data and metadata to create catalog table
catalog_df = review_df.merge(meta_df, how='left', on='asin')
catalog_df
```

```
[7]:
```

1.3.4 Visualizing the Data

In this section, we will proceed to visualize the distribution of our ratings as well as how many users gave how many ratings each.

```

[11]: # Check distribution of ratings
catalog_df['rating'].value_counts().sort_index(ascending=False)

```

```

[11]: 5.0    355360
      4.0    65885
      3.0    39428
      2.0    27830
      1.0    47608
      Name: rating, dtype: int64

```

```

[12]: # Check distribution of ratings in percent
catalog_df['rating'].value_counts(normalize=True).sort_index(ascending=False)

```

```

[12]: 5.0    0.662848
      4.0    0.122894
      3.0    0.073544
      2.0    0.051911
      1.0    0.088803
      Name: rating, dtype: float64

```

```

[13]: # Create bar plot of rating distribution
fig, ax = plt.subplots(figsize=(10,7))

```

```

g = sns.histplot(data=catalog_df, x='rating', hue='rating', palette='cool_r',
↳discrete=True, legend=True)

ax.set_title('Distribution of Ratings')
ax.set_xlabel('Rating')
ax.set_ylabel('Number of Reviews')
ax.set_xticks([1,2,3,4,5])
ax.legend(['66.3%', '12.3%', '7.3%', '5.1%', '8.9%']);

```

```

[14]: # Get number of ratings per user
freq_df = catalog_df.groupby('user').agg('count').reset_index()
freq_df

```

```

[14]:

1.3.5 Data Mapping

As mentioned before, due to the large size of this dataset, it is important to reduce the data to minimize the amount of memory being used. Hence, we map our ASIN and user codes to integer values in order to optimize memory allocation during the modeling process as well as converting our data types.

```
[19]: # Create list of unique asin codes
asin_list = catalog_df['asin'].unique()
```

```
[20]: # Create an array of integers to map asin codes to
np.arange(len(asin_list))
```

```
[20]: array([ 0, 1, 2, ..., 12108, 12109, 12110])
```

```
[21]: # Construct dictionary using asin and corresponding product code
asin_map = dict(zip(asin_list, np.arange(len(asin_list))))
```

```
[22]: # Check dictionary format
asin_map
```

```

1.3.6 Slicing Data for Modeling

We're almost ready to enter the modeling process, so let's go ahead and slice out just the columns we need to do so.

```
[33]: # Create dataframe with user item rating
df = catalog_df[['user', 'product_code', 'rating']]
```

```
[34]: # Save csv file to use in Databricks ALS model
# catalog_df.to_csv(r'data/Luxury_Beauty_reduced.csv', index=False)
```

1.4 Data Modeling

In this section, we will take a look at using the Surprise scikit package to test which algorithm will be the best for building a recommender system using our Amazon review data.

The models we will look at are some K-Nearest Neighbor models and a series of gridsearched Singular Value Decomposition models. You can find the process behind modeling using Alternating Least Squares in PySpark, but we will leave this model out of our main analysis due to its poor performance on this specific dataset as well as the fact that we will need to use PySpark to perform the modeling process.

```
[35]: # If using Colab, install Surprise
# %pip install scikit-surprise
```

```
[36]: # Import necessary packages for building recommender system
from surprise import Dataset, Reader
from surprise import accuracy
from surprise.prediction_algorithms import knns
from surprise.similarities import cosine, msd, pearson
from surprise.model_selection import cross_validate, train_test_split
from surprise.prediction_algorithms import SVD
from surprise.model_selection import GridSearchCV
```

```
[37]: # Create reader object and format review data for processing
reader = Reader(line_format = 'user item rating', sep = ',')
data = Dataset.load_from_df(df, reader=reader)
```

```
[38]: # Create train test split
trainset, testset = train_test_split(data, test_size=0.25, random_state=27)
```

1.4.1 KNN Basic

Before training our KNN models, we want to know how many unique values there are for items and users in order to determine which feature would be most efficient to calculate difference between. We will select the feature that has less unique values, which is the number of items as we will see.

```
[39]: # Check how many unique values for asin
catalog_df['product_code'].nunique()
```

```
[39]: 12111
```

```
[40]: # Check how many unique values for user
catalog_df['user'].nunique()
```

```
[40]: 416077
```

```
[41]: # KNN Basic with cosine similarity
KNN_basic_cos = knns.KNNBasic(sim_options={'name': 'cosine',
                                             'user_based': False}).fit(trainset)
cross_validate(KNN_basic_cos, data, verbose= True, n_jobs=-1)
```

Computing the cosine similarity matrix...

Done computing similarity matrix.

Evaluating RMSE, MAE of algorithm KNNBasic on 5 split(s).

	Fold 1	Fold 2	Fold 3	Fold 4	Fold 5	Mean	Std
RMSE (testset)	1.2632	1.2684	1.2633	1.2602	1.2582	1.2627	0.0035
MAE (testset)	0.9401	0.9429	0.9395	0.9383	0.9365	0.9395	0.0021
Fit time	22.04	23.50	19.74	17.16	15.13	19.51	3.07

```

```
RMSE: 1.2171
1.2171440876076423
MAE: 0.9237
0.9237444509387739
```

Great! We can see that by using our gridsearches, we were able to make some improvements in the RMSE score between iterations. It also looks like our SVD model has a lower RMSE score than even

our best performing KNN Baseline model, so we will move forward to building our recommender system using the SVD model with the best parameters found in our final gridsearch. We can also see that our MAE score is 0.9237, meaning that in terms of rating stars, the average error of our model is off by 0.9237 stars from the actual rating.

1.5 Evaluation

In this section, we will build some functions to assist the client in looking up product codes, as well as building a recommender system that takes a list of preferred products and returns a list of items that the user would likely give a high rating to.

1.5.1 Searching Product Codes

Here, we create a reduced catalog of product names with their corresponding product codes. We then build a function to search the name of a product to assist our user in looking up product codes to input into the recommender system.

```
[58]: # Set pandas options to increase max column width and row number
pd.options.display.max_colwidth = 100
pd.options.display.max_rows = 500
catalog_df
```

1.5.2 Building the Recommender System

In this section, we will take the hyperparameters from our best performing SVD model to build a usable recommender system. Upon running the function, the user will be prompted to enter a list of product codes of products that they gave high ratings to, and they will be given a list of products that our algorithm would recommend.

```
[62]: # Check last user number
df['user'].sort_values().tail()
```

```
[62]: 538073    416072
      538074    416073
      538075    416074
      538079    416075
      538080    416076
      Name: user, dtype: int32
```

```
[63]: # Create function to train model on full dataset and return recommendations
def user_ratings(lr_all=0.025, n_epochs=50, n_factors=150, reg_all=0.1,
    ↪random_state=27):
```

```

"""
Prompts user to enter customer's preferred product codes, models SVD
using ideal hyperparameters, and returns however many predictions
the user requests.

Args:
    lr_all : The learning rate for all parameters. Default is ``0.025``.
    n_epochs : The number of iteration of the SGD procedure. Default is
        ``50``.
    n_factors : The number of factors. Default is ``150``.
    reg_all : The regularization term for all parameters. Default is
        ``0.1``.
    random_state (int) : Determines the RNG that will be used for
        initialization. If int, ``random_state`` will be used as a seed
        for a new RNG. This is useful to get the same initialization over
        multiple calls to ``fit()``. If RandomState instance, this same
        instance is used as RNG. If ``None``, the current RNG from numpy
        is used. Default is ``27``.

Returns:
    rec_list (DataFrame) : DataFrame recommendations based on new user's
    preferred products.
"""

# Prompt user for list of product codes
list_of_products = [int(x) for x in \
    input('Enter product codes preferred by customer_\
→(separate by spaces): ').split()]

1.6 Conclusions

And there we have our final product recommendations! We can see that the Singular Value Decomposition had the best performance with respect to RMSE. Upon running a series of gridsearches, we were also able to determine the optimal hyperparameters to further reduce the RMSE score.

To interpret our error, we looked at the MAE score which was 0.9237 on our final best model, meaning that the average error of our model is off by 0.9237 stars from the actual rating.

Finally, we built out functions to help us look up product codes to put into a recommender system which would then provide us with however many product recommendations the user desires.

The value of this project lies in the ability to use Amazon's huge amount of ratings data to identify what other products a smaller retailer might want to consider adding to their inventory. The only additional data that we would need from the retailer would be customer preferences on the products that the retailer currently carries and that the customer would give high ratings to, and we can place this information in the context of Amazon's ratings to determine what other products this customer would be likely to give high ratings to.

A limitation to this analysis is that the dataset only contains beauty products under the "Luxury

Beauty” category, which is a collection of approved brands. Amazon also has a category labeled “All Beauty” whose data we have omitted in this analysis due to hardware limitations that would occur under the stress of dealing with the such a large size of these combined datasets.

To summarize, here are the final recommendations for our client:

1. In order to build a similar recommender system, SVD would be the best algorithm to use, with the following hyperparameters: `lr_all=0.025`, `n_epochs=50`, `n_factors=150`, `reg_all=0.1`
2. Client should carry the following products based on popularity on Amazon:
 - TOPPIK Hair Building Fibers
 - HOT TOOLS Professional 24k Gold Extra-Long Barrel Curling Iron/Wand
 - Mario Badescu Facial Spray with Aloe, Herbs and Rosewater
 - OPI Nail Lacquer, Cajun Shrimp
 - OPI Nail Lacquer, Not So Bora-Bora-ing Pink
 - BaBylissPRO Ceramix Xtreme Dryer
 - OPI Nail Envy Nail Strengtheners
 - Proraso Shaving Soap in a Bowl, Refreshing and Toning
3. Assuming that our client’s current customers would give high ratings to those products, our client should also consider carrying the following products:
 - Crabtree & Evelyn - Gardener’s Ultra-Moisturising Hand Therapy Pump
 - Crabtree & Evelyn Hand Soap, Gardeners
 - Soy Milk Hand Crème
 - Paul Mitchell Shampoo One
 - Glytone Rejuvenating Mask
 - PCA SKIN Protecting Hydrator Broad Spectrum SPF 30
 - jane iredale Amazing Base Loose Mineral Powder
 - jane iredale So-Bronze, Bronzing Powder
 - YU-Be: Japan’s secret for dry skin relief. Deep hydrating moisturizing cream for face, hand and body
 - Calvin Klein ETERNITY Eau de Parfum

Although ALS has been proven to be an effective algorithm in recommender systems, it was surprising to see such a poor performance score with the data used in this analysis. Moving forward, it might be a worthwhile investigation to see how the model performs if we combine data from the “All Beauty” category with the data used in this analysis.
